### MOTIVATIONS - ENSEMBLE AVERAGES

Recent developments suggest

Gravitation Path Integrals (GPI) computes quantities in Ensemble Averaged Theories

(e.g. Jackiw-Teitelboim gravity is dual to random matrix theories )

• E.g. Spectral 2-point function  $\langle |Z(\beta + iT)|^2 \rangle_J$  (Saad, Shenker, Stanford, 2018)

### MOTIVATIONS - ENSEMBLE AVERAGES

Recent developments suggest

Gravitation Path Integrals (GPI) computes quantities in Ensemble Averaged Theories

(e.g. Jackiw-Teitelboim gravity is dual to random matrix theories )

E.g. A topological model of "Baby universes" ( Marolf, Maxfield, 2020 )

**3**

$$
\left\langle Z[J_1]\cdots Z[J_n]\right\rangle:=\int_{\Phi\sim J} \mathcal{D}\Phi \,e^{-S[\Phi]} \hspace{1cm}\mathbf{3}^{-1}\left\langle Z^n\right\rangle=\sum_{d=0}^\infty d^n p_d(\lambda),\hspace{0.5cm}p_d(\lambda)=e^{-\lambda}\frac{\lambda^d}{d!}
$$
\n
$$
\left\langle Z[J_1]Z[J_2]\right\rangle=\bigodot\left(\bigodot\right)+\bigodot\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot\right)\left(\bigodot
$$

### MOTIVATIONS - ENSEMBLE AVERAGES

Recent developments suggest

Gravitation Path Integrals (GPI) computes quantities in Ensemble Averaged Theories

Other discussions about ensemble averages

…

## MOTIVATIONS - RANDOMNESS

**Cuestions:** 

How should we understand the ensemble average of random theories ? No such averages in familiar examples, don't know how to quantize

- ${\bf dea.}$  Idea:
	- $\triangleright$  Models with true randomness
	- $\triangleright$  Microscopic model that display

pseudo-randomness after coarse graining

 $\triangleright$  The true randomness is an analogue

of the pseudo-randomness

 $\triangleright$  Emergent pseudo-randomness and emergent gravity

# ENSEMBLE AVERAGES - DISCRETE DISTRIBUTIONS

- **Previous analyses focus on Gaussian distributions** 
	- Simple
	- ❖ Well studied
- We consider discrete Poisson distributions
	- ◆ Quantum theories have discrete Hilbert space
	- ◆ Discrete distributions could appear in GPI (Marolf, Maxfield 2020)

Under control

# ENSEMBLE AVERAGES - THE MODEL

- In practice, we consider  $\mathcal{L}(\phi) = \partial_{\mu} \phi \partial^{\mu} \phi J \phi$  where  $J = J_0(x) + J_1(x)$ 
	- $\triangleright$   $J_0(x)$  a classical source
	- $\triangleright$   $J_1(x)$  a random source
- **Integrate over the random source to get an effective action**

$$
e^{-S_{\rm eff}} = \int \mathcal{D}J_1(x)\mathcal{P}(J_1(x))e^{-\int dV(x)\mathcal{L}(\phi)}
$$

- **Cuestions:** 
	- $\triangleright$  What set of theories/sources to be included ?
	- $\triangleright$  What is the measure for the average ?

# ENSEMBLE AVERAGES - THE RANDOMNESS

A sensible choice is ( the physical description ):

$$
P(J_1(x)) = \prod_n \text{Pois}(J_1(x_n)dV(x_n), \lambda(x_n)dV(x_n)), \quad \forall dV(x_n) \text{ s.t. } \sum_n dV(x_n) = \mathcal{M}
$$
  
here  $\text{Pois}(m, \lambda) = e^{-\lambda} \frac{\lambda^m}{m!}, \quad m \in \mathbb{Z}_+$  and  $\lambda(x)dV(x) = \langle J_1(x)dV(x) \rangle_{J_1}$ 

where 
$$
\text{Pois}(m, \lambda) = e^{-\lambda} \frac{\lambda^m}{m!}
$$
,  $m \in \mathbb{Z}_+$  and  $\lambda(x)dV(x) = \langle J_1(x)dV(x) \rangle_{J_1}$ 

Properties:

- The distribution is local (x-dependent)
- $\triangleright$  The discretization  $dV(x)$  enters the probability distribution
- $\blacktriangleright$  The "fluxes" obey the discrete distribution
- Shape of the distribution measured by  $\lambda(x)$  **8**

# ENSEMBLE AVERAGES - THE RANDOMNESS

A sensible choice is ( the physical description ):

$$
P(J_1(x)) = \prod_n \text{Pois}(J_1(x_n)dV(x_n), \lambda(x_n)dV(x_n)), \quad \forall dV(x_n) \text{ s.t. } \sum_n dV(x_n) = \mathcal{M}
$$
  
here  $\text{Pois}(m, \lambda) = e^{-\lambda} \frac{\lambda^m}{m!}, \quad m \in \mathbb{Z}_+$  and  $\lambda(x)dV(x) = \langle J_1(x)dV(x) \rangle_{J_1}$ 

where 
$$
\text{Pois}(m, \lambda) = e^{-\lambda} \frac{\lambda^m}{m!}
$$
,  $m \in \mathbb{Z}_+$  and  $\lambda(x)dV(x) = \langle J_1(x)dV(x) \rangle_{J_1}$ 

Properties:

- The distribution is <u>local</u> (x-dependent)
- The discretization  $dV(x)$  enters the probability distribution
- Fig. 1. The "fluxes" obey the discrete distribution  $\int J_1(x) dV(x) \approx J_1(x) dV(x) \in \mathbb{Z}_+$
- $\triangleright$  "Shape" of the distribution measured by  $\lambda(x)$  **3**

## ENSEMBLE AVERAGES - THE EFECTIVE ACTION I

Averaging over the random source with this measure leads to

$$
\langle e^{\int dV(x)J_1(x)\phi(x)} \rangle_{J_1}
$$
\n
$$
= \left( \prod_n \sum_{k=0}^{\infty} \text{Pois}(J_1(x_n) dV(x_n) = k, dV(x_n) \lambda(x_n)) \right) e^{\sum_{k=0}^{\infty} dV(x_n)(J_1(x_n)(\phi(x_n) + i\pi) + 2\lambda(x))}
$$
\n
$$
= \exp \left( \int dV(x) \lambda(x) (e^{\phi(x)} - 1) \right)
$$
\ng back the other terms gives the effective action\n
$$
S_{\text{eff}} = \int dV(x) \left( \partial_\mu \phi \partial^\mu \phi - J_0(x) \phi - \lambda(x) (e^{\phi(x)} - 1) \right)
$$
\nalized Liouville theory\n
$$
\left( \text{I.}
$$

Adding back the other terms gives the effective action

$$
S_{\text{eff}} = \int dV(x) \Big( \partial_{\mu} \phi \partial^{\mu} \phi - J_0(x) \phi - \lambda(x) (e^{\phi(x)} - 1) \Big)
$$

Generalized Liouville theory

The sign of the potential term is "wrong"

- To cure this we consider instead the integration measure  $(J_1(x)) = \prod \text{Pois}\left( J_1(x_n) dV(x_n), \lambda(x_n) dV(x_n) \right) (-1)^{\mathcal{F}}, \quad (-1)^{\mathcal{F}}$ *n*  $J_1(x) = \prod \text{Pois}(J_1(x_n)dV(x_n), \lambda(x_n)dV(x_n))$  (-1)<sup>F</sup>, (-1)<sup>F</sup> = (-1)<sup> $J_1(x)dV(x)$ </sup>  $e^{2\int dV(x)\lambda(x)}$ normalization  $(-1)^{\mathcal{F}} \equiv (-1)^{\int J_1(x) dV(x)} e^{2 \int dV(x) \lambda(x)}$  $(-1)^{\mathcal{F}} \equiv (-1)^{\int J_1(x) dV(x)} e^{2 \int dV(x) \lambda(x)}$  $1)^{x} \equiv (-1)$ **EHVERAGES – THE SIGN**<br>
potential term is "wrong"<br>
consider instead the integration measure<br>  $\text{ois}(J_1(x_o)dV(x_o),\lambda(x_o)dV(x_o))(-1)^x$ ,  $(-1)^x \equiv (-1)^{\int_{J_1(x)dV(x)}^{J_2(x)dV(x)} e^{\frac{2\int dV(x)\lambda(x_o)}{\text{normalization}}}}$ <br>
a averaged action<br>  $S_{\text{eff}} = \int dV(x)\Big(\$
- This leads to the averaged action

$$
S_{\rm eff} = \int dV(x) \Big( \partial_{\mu} \phi \partial^{\mu} \phi - J_0(x) \phi + \lambda(x) (e^{\phi(x)} - 1) \Big)
$$

Is there a more accurate description of what we did?

• Consider the same theory, now reconsider it in terms of the Poisson Process.

### Definition: Poisson process

A random countable subset  $\Pi$  on a given carrier space  $\mathcal{M}$ , s.t.

- $\triangleright$  For disjoint subsets  $A_i \subset \mathcal{M}$ , the random variable  $N(A_i) = \#(\Pi \cap A_i)$ 
	- are mutually independent

 $\triangleright N(A_i)$  satisfies the Poisson distribution Pois  $\mathbf{with} \quad \Lambda(A_i) = \mathbb{E}(N(A_i))$  $N(A_i)$  $\left( \frac{1}{l} \right)$  $(N(A_i), \Lambda(A_i)) = e^{-\Lambda(A_i)} \frac{\Lambda(A_i)^{N(A_i)}}{\Lambda(A_i)}$  $\Lambda$ <sub>*i*</sub>)</sub>  $\Lambda$  $(A_i)$ <sup> $N(A_i)$ </sup> *i*  $i^{j}$ *i*  $A(A_i)$ ,  $A(A_i) = e^{-A(A_i)} \frac{A(A_i)^{N(A_i)}}{P(A_i)}$ 

• Mean measure  $A(A)$ , determined by the intensity function  $\lambda(x)$ <br> $A(A) = \int_A \lambda(x) dV(x)$ 

 $\Lambda(A) = \int_A \lambda(x) dV(x)$ 

• Consider the same theory, now reconsider it in terms of the Poisson Process.

### Definition: Poisson process

A random countable subset  $\Pi$  on a given carrier space  $\mathcal{M}$ , s.t.

- $\triangleright$  For disjoint subsets  $A_i \subset \mathcal{M}$ , the random variable  $N(A_i) = \#(\Pi \cap A_i)$ 
	- are mutually independent
- $\triangleright N(A_i)$  satisfies the Poisson distribution Pois $(N(A_i), \Lambda(A_i)) = e^{-\Lambda(A_i)} \frac{N(A_i)}{N(A_i)}$ with  $\Lambda(A_i) = \mathbb{E}(N(A_i))$  $(N(A_i), \Lambda(A_i)) = e^{-\Lambda(A_i)} \frac{\Lambda(A_i)^{N(A_i)}}{\Lambda(A_i)}$  $\Lambda$ <sub>*i*</sub>)</sub>  $\Lambda$  $(A_i)$ <sup> $N(A_i)$ </sup> *i*  $i^{j}$ *i*  $A(A_i) \cdot A(A_i) = e^{-A(A_i)} \frac{A(A_i)^{N(A_i)}}{P(A_i)}$  $\Lambda(A_i) = e^{-\Lambda(A_i)} \frac{1 - (1 - \tau_i)}{1 - \tau_i}$
- Mean measure  $\Lambda(A)$ , determined by the intensity function  $A(A_i) = \mathbb{E}(N(A_i))$ <br> **easure**  $A(A)$ , determined by the intensity function  $\lambda(x)$ <br>  $A(A) = \int_A \lambda(x)dV(x)$

 $\Lambda(A) = \int_A \lambda(x) dV(x)$ 

# **1** *N* **PROCESS - INTERPRETATION**<br>the Poisson processes, we reinterpret our computation as follows:<br>so f the random source is identified with the random counting measure<br>esimal subset  $B = dV(x)$ , we get<br> $N(dx) = J_1(x)dV(x)$   $\longrightarrow \int d$

In terms of the Poisson processes, we reinterpret our computation as follows:

 $\triangleright$  The fluxes of the random source is identified with the random counting measure

$$
\int_B dV(x) J_1(x) = N(B)
$$

For infinitesimal subset  $B \sim dV(x)$  , we get

 $\int_{B} dV(x) J_1(x) = N(B)$ <br>  $V(x)$ , we get<br>  $\longrightarrow \int dV(x) J_1(x) \phi(x) = \int N(dx) \phi(x)$ <br>
urce is identified with the Laplace functional<br>  $\int_{B} dV(x) J_1(x) \phi(x) = \int_{B} N(dx) \phi(x)$ <br>  $\left[ 14 \int_{B} \phi(x) J_1(x) \phi(x) \right]$ 

<span id="page-13-0"></span> $\triangleright$  Average over the random source is identified with the Laplace functional

$$
\mathbb{E}[e^{\int dV(x)J_1(x)\phi(x)}] = \mathbb{E}[e^{\int N(dx)\phi(x)}]
$$

# POISSON PROCESS - LAPLACE FUNCTIONAL

Generically, the Laplace functional of a test function  $f(x)$  is

$$
\mathbb{E}\left[e^{\alpha \int_{\mathcal{M}} N(dx) f(x)}\right] = e^{\int_{\mathcal{M}} \Lambda(x) (e^{\alpha f(x)} - 1)}
$$

In our computation, we thus have

$$
\mathbb{E}\left[e^{\int dV(x)J_1(x)\phi(x)}\right] = e^{\int \mathcal{J}(dx)\phi(x)} = e^{\int \mathcal{J}(dx)(e^{\phi}(x)-1)}
$$
  
such we got previously  
e accomplished by an  $(-1)^{N(B)}$  factor  $P(N(B) = n)$ 

- Same as the result we got previously
- Sign flip can be accomplished by an  $(-1)^{N(B)}$  factor

functional of a test function 
$$
f(x)
$$
 is  
\n
$$
\int_{N(dx) f(x)}^{N(dx) f(x)} \left[ e^{\int_{\mathcal{M}} \Lambda(x) (e^{\alpha f(x)} - 1)} \right]
$$
\nthus have  
\n
$$
\int_{\phi(x)}^{N(dx)} \left[ \mathcal{E}[e^{\int_{\mathcal{M}} \Lambda(x) (e^{\alpha f(x)} - 1)} \right] = e^{\int_{\mathcal{M}} \Lambda(x) (e^{\alpha f(x)} - 1)}
$$
\nit previously  
\n
$$
\int_{R(x)}^{R(x)} \left[ e^{\int_{\mathcal{M}} \Lambda(x) (e^{\alpha f(x)} - 1)} \right]
$$
\nished by an  $(-1)^{N(B)}$  factor  
\n
$$
P(N(B) = n) = \frac{(-\Lambda(B))^n}{n!} e^{\Lambda(B)}
$$

# ENSEMBLE AVERAGES - A SHORT SUMMARY

### What we have done is similar to the known example

- We have demonstrated the importance of choosing
	- $\triangleright$  which set of theories to be averaged over (fluxes but not sources)
	- > what is an appropriate measure for the average (the  $(-1)^{\mathcal{F}}$  factor)

# MICROSTATES - RATIONALE

■ Recap:

the ensemble average of random potentials could be an analogue of some pseudorandomness originated from the ignorance of some microscopic structure

- We will
	- Construct a microscopic model
	- Go to a special double scaled, low energy limit
	- **Illustrate how pseudo-randomness appears**
	- Demonstrate its equivalence to the type of true randomness we have discussed previously

### MICROSTATES - A REALIZATION

- A lattice, sites labelled by a position vector  $x$
- On each site: A complex fermion :  $\bar{\psi}_x |0\rangle = |1\rangle$ ,  $N_x = \bar{\psi}_x \psi_x$ ,  $N_x |i\rangle = i |i\rangle$ ,  $i = 0,1$ A real boson:  $\phi_{\rm x}$
- The Hamiltonian of the system:

A lattice, sites labeled by a position vector 
$$
x
$$
  
\nOn each site: A complex fermion:  $\overline{\psi}_x |0\rangle = |1\rangle$ ,  $N_x = \overline{\psi}_x \psi_x$ ,  $N_x |i\rangle = i |i\rangle$ ,  $i = 0,1$   
\nA real boson:  $\phi_x$   
\nThe Hamiltonian of the system:  
\n
$$
H = \sum_x H_{x,0} + H_{x,1}, \quad H_{x,0} = \prod_x^2 + \frac{M}{2} \phi_x^2 + \sum_y t_{xy} \phi_x \phi_y + J_0(x) \phi_x, \quad H_{x,1} = m \overline{\psi}_x \psi_x - \overline{\psi}_x \psi_x \phi_x
$$
\nPrepare the system in the state  
\n $\rho = \rho_\phi \otimes \rho_\psi, \qquad \rho_\psi = \bigotimes_x \rho_x, \qquad \rho_x = (1 - p(x)) |0\rangle_x \langle 0| + p(x) |1\rangle_x \langle 1|$   
\nwhere  $p(x)$  is the probability of fermionic excited state on site  $x$ 

**Prepare the system in the state** 

$$
\rho = \rho_{\phi} \otimes \rho_{\psi}, \qquad \rho_{\psi} = \bigotimes_{x} \rho_{x}, \qquad \rho_{x} = (1 - p(x)) |0\rangle_{x} \langle 0| + p(x) |1\rangle_{x} \langle 1|
$$

where  $\ p(x)$  is the probability of fermionic excited state on site  $\ x$ 

Consider the continuous limit:  $1$  $n = \frac{d}{d} \rightarrow \infty$ *a*  $=$   $\longrightarrow \infty$ 

where  $a$  is the lattice spacing,  $\,n\,$  is the number of site per unit volume

- In this limit, countable infinite lattice sites in each open set.
- Further a double scaling limit: the number of sites (per unit volume) where fermionic d.o.f. is excited remains finite

![](_page_18_Picture_6.jpeg)

### MICROSTATES - A DOUBLE SCALED LIMIT

**The fermionic factor of the density matric in a small enough subset**  $dV(x)$  is

**IICROS THAT ES - A DOUBLE SCALED LIMIT**  
\nthe fermionic factor of the density matrix in a small enough subset 
$$
dV(x)
$$
 is  
\n
$$
\bigotimes_{x \in dV(x)} \rho_x = \bigotimes_{x \in dV(x)} (1 - p(x)) |0\rangle_x \langle 0| + p(x) |1\rangle_x \langle 1|
$$
\n
$$
= \sum_{k} P(n_x = k) (|0\rangle_x \langle 0|)^{\otimes (n' - k)} \otimes (|1\rangle_x \langle 1|)^{\otimes k}
$$
\n
$$
P(n_x = k) = \binom{n'}{k} p(x)^k (1 - p(x))^{n' - k}
$$

In the above limit,  $P(n_x = k)$  becomes

$$
= \sum_{k} P(n_{x} = k) (|0\rangle_{x} \langle 0|)^{\otimes (n-k)} \otimes (|1\rangle_{x} \langle 1|)^{\otimes k} \qquad P(n_{x} = k) = {n \choose k} p(x)^{k} (1 - p(x))^{n-k}
$$
  
the above limit,  $P(n_{x} = k)$  becomes  

$$
\lim_{n \to \infty} P_{dx} (n_{x} = k) = \frac{n'!}{k! (n' - k)! n'^{k}} (n'p)^{k} (1 - \frac{n'p}{n'})^{n' - k} = \frac{\Lambda_{dx}(x)^{k}}{k!} e^{-\Lambda_{dx}(x)} = P_{\text{Pois}}(k, \Lambda_{dx}(x))
$$
  
oisson distribution with  $\Lambda_{dx}(x) = \lambda(x) dV(x)$ .

a Poisson distribution with  $\Lambda_{dx}(x) = \lambda(x) dV(x)$ .

### MICROSTATES - TRACING OUT FERMIONS

• Next we get an effective action for the bosonic field  $\phi_x$ 

**Integrating over the fermionic degrees of freedom** 

effective action for the bosonic field 
$$
\phi_x
$$
  
\nthe fermionic degrees of freedom  
\n
$$
e^{-\beta H_{\rm eff}} = \text{Tr}_{\mathcal{H}_{\psi}} ((-1)^F \rho e^{-\beta H}) = \text{Tr}_{\mathcal{H}_{\psi}} (\rho e^{-\beta H + i\pi F}) := \text{STr}_{\mathcal{H}_{\psi}} (\rho e^{-\beta H})
$$
\n
$$
\text{chosen so that it is base free}
$$

Such a trace is chosen so that it is base free

Tracing over the fermions leads to

**MICROSIATES** - TRACING OUT FERMIONS  
\nTracing over the fermions leads to  
\n
$$
e^{-\beta H_{\text{eff}}} = \text{Tr}_{\gamma_{t_o}} \left( \bigotimes_{dV(x)} \rho_x e^{-\beta \sum_{dV(x)} \left( \sum_{dV(x)} \left( H_x \frac{ia}{\beta} E_{\text{in}} \right) \right)} \right) = \prod_{dV(x)} \left( \sum_k \text{Pois}(k, \Lambda_{dx}(x)) e^{-\beta \left( k(m - \phi_x - \frac{i\pi}{\beta}) \right)} \right) = e^{-\beta \int dV(x) \frac{2(x)}{\beta} \left( e^{-\beta (m - \phi_x - \frac{i\pi}{\beta})} \right)}.
$$
\nReducing  $b = \frac{\beta}{2}, \qquad \mu = \frac{\lambda}{2\pi\beta} e^{-\beta m} = \frac{\lambda}{4\pi b} e^{-2bm}$ ,  
\nand adding back the pure bosonic terms, we get  
\n
$$
\mathcal{H}_{\text{eff}}(x) = \pi_x^2 + \frac{M}{2} \phi_x^2 + \sum_{y} t_{xy} \phi_x \phi_y + J_0(x) \phi(x) + 2\pi \mu(x) e^{2\phi_x} + \frac{\lambda(x)}{2b}
$$

$$
\textbf{Redefining} \quad b = \frac{\beta}{2}, \qquad \mu = \frac{\lambda}{2\pi\beta} e^{-\beta m} = \frac{\lambda}{4\pi b} e^{-2bm} \quad ,
$$

and adding back the pure bosonic terms, we get

$$
\mathcal{H}_{\rm eff}(x) = \pi_x^2 + \frac{M}{2} \phi_x^2 + \sum_{y} t_{xy} \phi_x \phi_y + J_0(x) \phi(x) + 2\pi \mu(x) e^{2b\phi_x} + \frac{\lambda(x)}{2b}
$$

![](_page_21_Picture_6.jpeg)

### MICROSTATES - THE LOW ENERGY LIMIT

Take the low energy limit by focusing on the lowest few Fourier modes

- **For simplicity, we choose**  $t_{xy} = t_{yx} = \frac{1}{2} t \delta \left( ||x-y|| -1 \right)$  $t_{xy} = t_{yx} = \frac{1}{2}t\delta(\|x-y\|-1)$
- The low energy effective theory is

plicity, we choose

\n
$$
t_{xy} = t_{yx} = \frac{1}{2} t \delta \left( \|x - y\| - 1 \right)
$$
\nenergy effective theory is

\n
$$
\mathcal{H}_{\text{eff}}(x) = \pi_x^2 + \frac{1}{c^2} \left( \partial_x \phi(x) \right)^2 + m_\phi^2 \phi(x)^2 - J_0(x) \phi(x) + 2\pi \mu(x) e^{2b\phi(x)} + \frac{\lambda(x)}{2b}
$$
\n
$$
m_\phi^2 = \frac{M}{2} - t, \qquad c^2 = \frac{2}{a^2 t} \ge 0, \qquad m_\phi, a, c \in \mathbb{R}
$$

where

$$
m_{\phi}^2 = \frac{M}{2} - t
$$
,  $c^2 = \frac{2}{a^2 t} \ge 0$ ,  $m_{\phi}, a, c \in \mathbb{R}$

$$

**- The range of parameter is**  $\frac{M}{\phi} = 2(1 + \frac{m_{\phi}^2}{2}) \geq 2$ *t t*  $=2(1+\frac{m_{\phi}}{2})\geq 2$ 

• A branch cut at  $m_{\phi}=0$  , corresponding to integrating out a massless mode.

# A GRAVITY INTERPRETATION?

- In previous analyses, probabilistic measures emerge. Interpret it as a geometric volume measure in gravity ?
- This helps understand Gravitational Path Integral = Ensemble Average of Theories
- Recall our effective action

$$
S_{\text{eff}} = \int dV(x) \Big( \partial_{\mu}^{\mu} \phi \partial \phi(x) - J_0(x) \phi + \lambda(x) (e^{\phi(x)} - 1) \Big)
$$

and the Liouville gravity action

$$
S_{\rm L} = \frac{1}{4\pi} \int d^2x \sqrt{|h|} \left( Q\Phi(x) R_h(x) + (\nabla \Phi)^2 + 4\pi \mu e^{2b\Phi(x)} \right)
$$

# A GRAVITY INTERPRETATION ?

Comparing the actions, we find they are identical once we identify

$$
Q\sqrt{|h|}R_h(x) = -J_0(x), \qquad 4\pi\mu\sqrt{|h|} = \frac{\lambda(x)}{2b}e^{-2mb}, \qquad \sqrt{|h|}h^{\mu\nu}\partial_\mu\partial_\nu = \delta^{\mu\nu}\partial_\mu\partial_\nu
$$

• The last relation trivializes in the conformal gauge  $h_{\mu\nu} = e^{\rho(x)} \delta_{\mu\nu}$ , and the remaining two relations become

$$
Q\delta^{\mu\nu}\partial_{\mu}\partial_{\nu}\rho(x) = J_0(x), \qquad 4\pi\mu e^{\rho(x)} = \frac{\lambda(x)}{2b}e^{-2mb}
$$

 This gives the relation between the probabilistic measure and the geometric measure  $\lambda(x)$  $\rho(x)$ 

# A GRAVITY INTERPRETATION ?

- Comments
- 1. This connection is only true if  $J_0(x)$  correlates with  $\lambda(x)$  according to ( ) *<sup>x</sup>*

$$
J_0(x) = Q\delta^{\mu\nu}\partial_\mu\partial_\nu \log(\lambda(x))
$$

i.e. not all average of random theories have gravity descriptions

- 2. Curiously  $J_0(x)$  was introduced as a source of  $\phi(x)$ :  $J_0(x) = \delta^{\mu\nu}\partial_\mu\partial_\nu\phi(x)$ . Recall  $e^{\phi(x)}$ is originally the Weyl factor in getting Liouville; this put  $\lambda(x)$  and  $\ e^{\phi(x)}$  on the same footing, and confirms the geometric interpretation of  $\lambda(x)$
- 3. The parameter  $Q$  sets up a scale.
- 4. The gravity description only captures the "mean" probability measure  $\lambda(x)$ , but not the details of the microscopic model. They could encode the information of the footing, and confirms the geometric interpretation of  $\lambda(x)$ <br>The parameter  $Q$  sets up a scale.<br>The gravity description only captures the "mean" probability measure  $\lambda(x)$ <br>the details of the microscopic model. They could  $\lambda(x)$ , but not

### SUMMARY

- Quantum theories have discrete Hilbert spaces, so we consider averaging over theories with discrete random variables.
- Suitable ensemble average of these discrete theories, with a mathematically rigorous description in terms of Poisson processes.
- Averaged theories of this type have an equivalent description of tracing over parts of the microstates in a single theory.
- The results from both approaches mirror Liouville gravity.
